

The negative pole of the high-voltage cabinet is grounded after energy storage

How does a faulty pole affect the voltage magnitude?

Therefore, the voltage magnitude of the faulty pole decreases. As for the healthy pole (negative pole), the line-mode voltage change has opposite polarity to the pole voltage, which decreases the voltage magnitude, but the zero-mode voltage change has the same polarity with the pole voltage, which increases the voltage magnitude.

Can a negative DC pole be grounded on an inverter?

If PID has taken place, it can be mitigated by grounding the negative DC pole on the inverter in order to avoid negative voltages on the strings. This works if the inverter allows this operation mode and all the proper design action associated with this choice is taken.

What is the difference between a healthy pole and a zero-mode voltage?

As for the healthy pole (negative pole), the line-mode voltage change has opposite polarity to the pole voltage, which decreases the voltage magnitude, but the zero-mode voltage change has the same polarity with the pole voltage, which increases the voltage magnitude. Since Z_0 is greater than Z_1 , we have .

Should a negative pole be earthed instead of a positive pole?

According to IEC 60479-1, in 2-wire DC systems, it is recommended to earth the negative pole instead of the positive pole. This is because, earthing the positive pole drives the fault current direction to flow 'upwards' through the heart which can cause higher risk of the ventricular fibrillation.

What happens if a pole-to-ground fault occurs in a true bipolar grid?

After a pole-to-ground fault occurs in the true bipolar the MMC HVDC grid, the branches of non-fault pole bear only a small part of the discharge current of the fault pole. The currents in the branches of the non-fault pole could change, but the change is smaller than that of the currents in the corresponding branches of the fault pole.

What is low resistance grounding?

Low resistance grounding is proposed to mitigate high transient overvoltages during disturbances. Neutral point of AC side transformer ungrounded, DC bus midpoint grounded. Detection of pole voltage shift. Ground current monitoring. Reduces insulation requirements as touch voltage is half the nominal voltage. Protection of both poles required.
