What causes hot spots on solar panels?

Hot spots, one of the most common issues with solar systems, occur when areas on a solar panel become overloaded and reach high temperatures relative to the rest of the panel. When current flows through solar cells, any resistance within the cells converts this current into heat losses.

Why do I have dark spots on my solar panels?

Without a secure seal, moisture and air can enter the system, causing corrosion and substantially reducing panel performance. If you see dark spots on your panels, this could be a sign that your panels are undergoing delamination, and you should contact your installer for an inspection.

Why do solar cells have discoloured snail trails?

If water vapour is also present, discoloured snail trails are formed along the microcracks to not only reduce energy production but also compromise appearance. Snail trails can be signs of microcracks in the underlying solar cells.

What happens if you put a hotspot on a solar panel?

Hotspots can lead to major consequences. To begin with, hotspots on solar panels will bring down your power output. The difference in the generation might not stand out in the short run. But in the long run, the same minor difference can turn into a significant power loss. And the problems don't end here.

How do I know if my PV panel is delaminated?

Usually the process starts at one angle or a side of the panel and then spreads across the PV module. You can detect the start of delamination by bubbles and creases on the plastic rear surface. Some owners try using duct tape and sealant to slow the process down, but such a panel isn't going to last long.
